ABSTRACT

Opportunistic infections are common and in the cases of HIV/AIDS they are very harmful. Fungi isolated from HIV/AIDS positive patients were tested for their sensitivity to essential oils from Cymbopogon citratus, Cymbopogon martini, Cinnamomum zeylanicum, Rosmarinus officinalis, Mentha piperita, Pelargonium graveolens, and Vitex negundo. In agar well diffusion method the selected essential oils were effective against all forms such as yeast, yeast like fungi and molds and mostly comparable to the standard reference antifungal drug miconazole (100 µg). The minimal inhibitory concentration (MIC) of C. citratus and C. martini were effective but to the least level, when compared with the reference drug. The MIC of C. zeylanicum was best and very much comparable to the reference drug. The MIC of R. officinalis was variable from more effective to least effective against different test organisms. The MIC of M. piperita was effective but to the least level (1000 µg/ml), when compared with the reference drug. The MIC of P. graveolens, was effective but to the least level (500 µg/ml), when compared with the reference drug. The MIC of V. negundo was effective but to the least level (500 µg/ml), when compared with the reference drug. The results for minimum fungicidal concentration (MFC) were similar to MIC results, but in MBC confirmation was made by the absence of visible growth in culture media. The antifungal activity is attributed to the components of essential oils, which mostly interferes with the cell membrane structure and function. According to the results of this study, the essential oil or their ethanol extract of those essential oils may be suggested as a new potential source of natural antimicrobial for the prevention, treatment and control of fungal diseases in various patients, particularly, for HIV/AIDS patients.

Key words: Antifungal activity, opportunistic fungi, HIV/AIDS, essential oils, aromatherapy.

INTRODUCTION

Before the widespread use of potent combination antiretroviral therapy (ART), opportunistic infections (OIs), which have been defined as infections that are more frequent or more severe because of immunosuppression in HIV-infected persons, were the principal cause of morbidity and mortality in this population. In the early 1990s, the use of chemoprophylaxis, immunization, and better strategies for managing acute OIs contributed to improved quality of life and improved survival (1). Although hospitalizations and deaths have decreased since the implementation of ART, OIs remain a leading cause of morbidity and mortality in HIV-infected persons (2)(3)(4)(5)(6)(7)(8)(9)(10).

In recent years there has been an increasing interest in the use of natural substances, and some questions concerning the safety of synthetic compounds have encouraged more detailed studies of plant resources. Essential oils, odors and volatile products of plant secondary metabolism, have a wide application in folk medicine as well as in fragrance industries. Essential oils are complex natural mixtures of volatile secondary metabolites, isolated from plants by hydro- or steam-distillation. The main constituents of essential oils, for example, monoterpenes and sesquiterpenes and phenylpropanoids including carbohydrates, alcohols, ethers, aldehydes and ketones, are responsible for the fragrant and biological properties of aromatic and medicinal plants (11) Various essential oils and their components possess pharmacological effects, demonstrating anti-inflammatory, antioxidant and anti-cancerogenetic properties (12)(13)(14). In addition to inducing resistance, antibiotics are sometimes associated with opposing effects such as hypersensitivity, immune-suppression and allergic reactions (15). Therefore, there is a need to develop alternative antimicrobial drugs for the treatment of infectious diseases (16) (17).

It is important to investigate scientifically those plants which have been used in traditional medicines as potential sources of novel antimicrobial compounds (18). Also, the resurgence of interest in natural therapies and increasing consumer demand for effective, safe, natural products means that quantitative data on plant oils and extracts are required. Various publications have documented the antimicrobial activity of essential oils and plant extracts including rosemary, peppermint, bay, basil, tea tree, celery seed and fennel (19)(20)(21)(22)(23). All the oils tested exhibited different degrees of antifungal activity against A. fumigatus and A. niger. The maximum antymycotic activity was shown by C. martini followed by C. citratus, Eucalyptus globulus and C. zeylenicum. Aggarwal, et al. (24) reported antymycotic activity of C. martini against A. niger. The oil of C. citratus was effective against fungal pathogens causing diseases in plants and human beings (25). Quale, et al. (26) treated infections caused by
Candida in AIDS patients with a drug based on Cinnamon. In our study we also found that essential oil extracted from C. zeylanicum demonstrated strong antifungal activity on both the species of Aspergillus. The antimycotic activity of cinnamon bark due to presence of cinnamaldehyde is well known (27). Similarly, in vitro antimicrobial activity of C. zeylanicum (bark) against human pathogenic fungi and commensally bacteria was studied by (28) and (29). The oils of M.spicata, Azadirachta indica, Eugenia caryophyllata, Withania somnifera and Zingiber officinale exhibited moderate activity. The essential oil of mint was found to have strong antimycotic activity against C. albicans (30).

The main advantage of essential oils is that they can be used in any foods and are considered generally recognized as safe (GRAS) (31), as long as their maximum effects is attained with the minimum change in the organoleptic properties of the food. Such antimicrobial activity is due to the presence of bioactive substances such as flavonoids, terpenes, coumarines and carotenes (32). The objective of this work was to study the effect of the essential oils of Lemongrass oil, Palmarosa oil, Cinnamon bark oil, Rosemary oil, Geranium oil, Peppermint oil, and Chaste tree leaf oil on the growth of fungus commonly associated with opportunistic infections in HIV/AIDS patients.

**MATERIALS AND METHODS**

**Essential oils**

Seven essential oils such as Lemongrass oil (*Cymbopogon citratus*-Graminaceae), Palmarosa oil (*Cymbopogon martini*-Graminaceae), Cinnamon bark oil (*Cinnamomum zeylanicum*-Lauraceae), Rosemary oil (*Rosmarinus officinalis*-Labiatae), Geranium oil (*Pelargonium graveolens*-Geraniaceae), Peppermint oil (*Mentha piperita*-Labiatae), and Chaste tree leaf oil (*Vitex negundo*-Lamiaceae) were obtained from Aromax Trading Co, Chennai, Tamilnadu, India (commercial producers of plant essential oils and aromatic substances) were used in this study. Quality of the oils was ascertained to be more than 98% pure. The oil was stored in the dark at 4°C until used within a maximum period of one week.

**Test fungi**

Microorganisms (Clinical bacterial isolates from HIV infected) such as *Candida albicans Candida tropicalis Cryptococcus neoformans Aspergillus niger, Aspergillus flavus, Aspergillus fumigatus, Penicillium Sp, Mucor Spp, Rhizopus Spp* were obtained from the Microlabs, Institute of research and technology, Arcot, Vellore district, Tamilnadu, India. Sabouraud’s dextrose agar (SDA) and broth (SDB) were used for culturing of test fungi. All strains were stored at 20°C in the appropriate medium containing 10% glycerol and regenerated twice before use.

**Qualitative chemical analysis of essential oils**

The essential oils were subjected to qualitative chemical analysis for secondary metabolites, tannins, saponins, steroid, alkaloids, phenolics, terpenes and glycosides in accordance with (33) and (34) Harborne with little modification (35) and (36).
Results for agar well diffusion method

In agar well diffusion method the selected essential oils were effective against all forms such as yeast, yeast like fungi and molds. *C. citratus* was highly active against *Mucor spp* (14.25±0.97), *C. neoformans* (13.0±0.51) and least against *A. flavus* spp. (8.13±0.636) *C. martiiiius* was highly active against *C. albicans* (13.25±0.90), *C. tropicalis*, (13.16±0.53), *C. neoformans* (13.89±0.43) and least against *A. flavus* (11.03±0.48). *C. zeylanicum* was highly active against *C. neoformans* (21.83±0.74) *A. niger* (21.15±0.86), *C. albicans*, (19.23±0.80) and least against *Mucor spp* (11.87±0.77). *R. officinalis* was highly active against *Mucor spp* (14.8±0.70), *C. albicans* (13.12±0.80) and least against *A. flavus* (7.97±0.73). *M. piperita* was highly active against *Rhizopus spp* (21.06±0.67), *C. albicans* (19.40±0.73) and least against *A. niger* (9.03±0.58). *V. negundo* was highly active against *Rhizopus spp* (13.09±0.43), *A. niger* (13.03±0.81), *C. albicans* (12.09±0.59) and least against *C. tropicalis* (8.99±0.47). All fungi were found to be sensitive to all test essential oils and mostly comparable to the standard reference antifungal drug miconazole (100 µg).

Results for minimum inhibitory concentration (MIC) of essential oils

The minimal inhibitory concentration of *C. citratus* was 250 µg/ml against *C. albicans*, *C. tropicalis* and *C. neoformans* and it was 500 µg/ml for *A. niger*, *A. flavus*, *A. fumigatus* *Mucor spp* and *Rhizopus spp*. The results showed that they effective but to the least level, when compared with the reference drug miconazole. The minimal inhibitory concentration of *C. martiiiius* was similar to *C. citratus*.

The minimal inhibitory concentration of *C. zeylanicum* was 15.6 µg/ml against *C. albicans*, *C. tropicalis*, and *C. neoformans* and 31.25 µg/ml against *A. niger*, *A. flavus*, *A. fumigatus* *Mucor spp* and *Rhizopus spp*. The results were best and very much comparable to the reference drug.

The minimal inhibitory concentration of *R. officinalis* was 125 µg/ml against *C. albicans* and *C. tropicalis*, and it was 250 µg/ml *C. neoformans* and 500 µg/ml for *A. niger*, *A. flavus*, *A. fumigatus* *Mucor spp* and *Rhizopus spp*. The results showed that they were active against *C. albicans* and *C. tropicalis* effective; moderate to *C. neoformans* but to the least level against other organisms, when compared with the reference drug.

The minimal inhibitory concentration of *M. piperita* was 1000 µg/ml for all the test fungi. The minimal inhibitory concentration of *P. graveolens* was 500 µg/ml for all the test fungi. The minimal inhibitory concentration of *V. negundo* was 500 µg/ml for all the test fungi. The results showed that they were effective but to the least level, when compared with the reference drug.

Results for Minimum fungicidal concentration (MFC) of essential oils

The results for minimum fungicidal concentration (MFC) were similar to minimum inhibitory concentration (MIC) results, but in MBC confirmation was made by the absence of visible growth in culture media.

DISCUSSION

It is estimated that every minute, five people between the ages of 10 and 24 become infected with HIV somewhere in the world (42). Because HIV does not have to be reported in many states, the estimate is conservative (43). Approximately 50% of people with AIDS or HIV are using complementary and alternative modalities (CAMs) (44). Initially, HIV-positive or AIDS-infected people used CAM therapies that were thought to have immunostimulatory or antiviral properties (45). However, as antiretroviral drugs became more successful, patients began choosing to add CAMs to their conventional regimes for specific symptom relief (46). Although aromatherapy is a lesser known complementary therapy, it has much to offer nursing care of HIV/AIDS in particular for the control of resistant infections (47).

While the recognized definition states that “aromatherapy is the use of essential oils for therapeutic purposes” (48), the definition of clinical aromatherapy (as used in nursing) is more specific: “The use of essential oils for outcomes that are measurable” (49). The definition of essential oils is also very specific: “Essential oils are the steam distillate of aromatic plants” (50). Other kinds of extracts that are not obtained by steam distillation are not essential oils. Extracts may contain residues of allergenic solvents.

Lemongrass (*Cymbopogon citratus*) was found to be as effective in a 2.5% cream as four other commercial creams against ringworm and clinical isolates of four dermatophytes in vitro (51). Each of the commercial creams had clotrimazole, isoconazole nitrate, ketoconazole, benzoic acid, and salicylic acid as their main active ingredients.

It was found that essential oils were effective against both acute and chronic infections in humans. He also found that concentrations that were insufficient to kill the pathogenic organism in a laboratory were effective in humans. The example given was an in vitro minimum inhibitory concentration (MIC) of 0.00025 g/mL as opposed to an in vivo concentration of 0.000032 g/mL (52).

Geranium, cinnamom, and peppermint were found by Violion, et al., (53) to be effective in vitro against *Candida*. Citral is the generic name for two different isomeric aldehydes (geranial and neral) that are found in many essential oils. Citral is thought to be the component most likely to be antifungal (54) (Pattnaik et al., 1997). Onawunmi (55) found citrus to have antifungal properties in dilutions as low as 0.005% to 0.008%. Essential oils containing large amounts of citrus are melissa, verbena, and lemongrass. Aldehydes are best avoided on a damaged mucous membrane, but they can be used diluted on the skin. A component of essential oils found by Beylier and Givaudan (56) to have anti-candida properties is citronellol. Citronellol is an alcohol and is the main constituent of lemon grass and *Eucalyptus citriadora* (60%–80%). Alcohol is safe to use on the skin and the mucous membrane. Pattnaik et al., (57) reported that lemongrass, *Eucalyptus globulus*, palmarosa, and peppermint were the most effective essential oils tested against cryptococcus. Basil and thyme were not included in this study. (Lemongrass was effective not only against cryptococcus but against all 11 other fungi tested in low dilutions.)

The MIC for each of the four essential oils against cryptococcus was 5 L/mL. In another article, Pattnaik, et al. (58) found that complete essential oils were more effective against cryptococcus than the isolated, active component. There was one exception, lemongrass, which was equal to the isolated parts of citral and geraniial. Larrondo and Calvo (59) compared the topical and inhaled action of citral to the systemic effects of clotrimazole. Although the actual way essential oils work as fungicides is not completely clear, it appears that metabolism and growth of the fungus are inhibited, often with a breakdown in the lipid part of the membrane, resulting in increased permeability and/or rupture (60). Soliman et al., (61) tested essential oil of rosemary. They investigated the essential oil distilled from two plants growing in different climatic conditions. They found that both rosemary essential oils were effective against C. neoformans in vitro and recommended that either essential oil could be an effective treatment in AIDS patients with cryptococcal meningitis and pneumonia. Although both types of rosemary were effective, the effectiveness could have been due to a different chemical component in each oil. Many of the essential oils used showed good fungistatic action. The best effects were from palmarosa, geranium, savory, sandalwood, thyme, marjoram, and...
lavender that appeared to agree with the findings of Valnet(62) as discussed earlier in this article and could be related to the adaptogenic capacity of essential oils (and all plant medicines) to behave differently depending on the terrain they are in.

Lucini, et al.(63) indicated that mycelial growth inhibition is caused by the monoterpenes present in essential oils. These components would increase the concentration of lipidic peroxides such as hydroxyl, alkoxyl and alkoperoxy radicals and so bring about cell death. For Sharma and Tripathi (64), the EOs would act on the hyphae of the mycelium, provoking exit of components from the cytoplasm, the loss of rigidity and integrity of the hypha cell wall,
resulting in its collapse and death of the mycelium.

Only few substances are known to inhibit human pathogenic fungi, which are often completely resistant to antibiotics, and most of them are relatively toxic. The increased incidence of therapeutic failure in the treatment of fungal infections and the prevalence of opportunistic infections has renewed interest in the search for new antifungal agents, including those obtained from higher plants. Present results allow supposing that these natural compounds could be useful agents in the topical treatment of fungal infections. Medicinal plants have been used in developing countries as alternative treatments to health problems. Many plant extracts and essential oils isolated from plants have been shown to exert biological activity in vitro and in vivo, which justified research on traditional medicine focused on the characterization of antimicrobial activity of these plants (65). Brazil, Cuba, India, Jordan and Mexico are examples of countries that have a diverse flora and a rich tradition in the use of medicinal plants for both antibacterial and antifungal applications (66)(67)(68).

**Cryptococcus neoformans**, a fungus which causes infection during the last stages of AIDS is inhibited both by palmarosa oil and geraniol (96).

Potassium leakage from a different fungus, *C. albicans*, due to action of geraniol over a period of 2 h has been reported earlier (70). Palmarosa oil led to changes in the composition of the yeast cell membrane, with more saturated and less unsaturated fatty acids in the membrane after exposure of *S. cerevisiae* cells to the oil. Some of the palmarosa oil was lost by volatilization during incubation of the oil with the yeast cells. The actual concentration of the oil components affecting the yeast cells could not therefore be accurately determined (71).

Reports of some essential oils affecting membrane integrity include tea tree oil causing damage to membranes in *C. albicans* while other oils and their components have disrupted the permeability barrier of yeast cells (72). The fatty acid composition of microbial cell membranes affects their ability to survive in various environments (73). The ratio of saturated to unsaturated fatty acids can alter in response to environmental conditions (74). Maintenance of an optimal degree of fluidity of membrane lipids is important for normal function, with environmental adaptation known as homeoviscous adaptation (75)(76).

**Conclusions**

The essential oils as antimicrobial agents present two main characters: the first is their natural origin which means more safety to the people and the environment, the second is that they have been considered at low risk for resistance development by pathogenic microorganisms. The antifungal activity is attributed to the components of essential oils, which mostly interferes with the cell membrane structure and function. According to the results of this study, the essential oil or their ethanol extract of those essential oils may be suggested as a new potential source of natural antimicrobial for the prevention, treatment and control of fungal diseases in various patients, particularly, for HIV/AIDS patients.
